**Probing transferability of intermolecular interactions by their features:
a nitro group case study**

Ivan V. Ananyev and Leonid L. Fershtat

The description of the proposed methodology

1. A functional group having at least one geometrical contact with any atom X is searched in a structural database. The length of a contact must be not less than the sum of van der Waals radii but the more the better as one needs to generate reasonable promolecular density further. Lengths of covalent bonds with hydrogen atoms must be normalized.

Several functional groups forming contacts between each other can also do but their environment should be also stored by seeking for contacts of each atom of these groups with any atom to form rather large supramolecular cluster.

2. The Cartesian coordinates of functional group and its supramolecular surrounding are stored. In Cambridge Structural Database, the “export entries as” is used and the corresponding .cor file is inspected to combine all X atoms surrounding one functional group from one crystal structure.

The data for each supramolecular cluster are as follows: refcode from CSD, index of a functional group (can be more than 0 if several independent groups are presented in crystal), Cartesian coordinates of atoms from functional group and its surrounding.

3. Promolecular electron density is constructed for each supramolecular cluster and the (3,-1) critical points between functional group and its surrounding is searched for. Coordinates of critical points as well as their local properties (electron density value, Hessian, etc.) are added to the data of supramolecular cluster.

4. All supramolecular cluster are map onto each other by minimizing the root-mean-square deviation of functional group from each cluster with the functional group of some reference cluster (Kabsch algorithm, for instance).

This accumulate all the (3,-1) critical points in the one reference frame. Visually, these critical points are now looked like a cloud surrounding some averaged functional group. This cloud corresponds to the distribution of bonding interactions of this functional group in 3D real space.

5. The cloud can be analyzed at least in two ways: by inspecting of local properties at critical points (cloud would be colored by electron density values, for instance) or by inspecting of density of a cloud (cloud would be colored by some estimation of density distribution function; by that from Gaussian kernel estimator, for instance).

Table S1. Cartesian coordinates of CNO₂ fragments retrieved from Cambridge Structural Database and superposed onto each other to minimize root mean square deviations.

refcode atomnames X Y Z

Table S2. Properties of (3,-1) critical points of promolecular electron density between nitro group and its supramolecular surrounding. Cartesian coordinates (in Å) were obtained by superposing nitro groups, see Table S1. Other properties (a.u.) were obtained from the topography of promolecular electron density function in each supramolecular associate.
